SUMMARY2
Outcome 3
Demographics 3

Summary

This report provides information on total conventional hip replacement procedures performed with metal/metal bearing surfaces.

All hip replacement procedures recorded by the Registry from the commencement date to 31 December 2024 have been included in this report.

Summary data on the use of metal/metal bearings are provided, along with outcomes (revision rate, reason for revision and type of revision) according to patient and implant characteristics (e.g. head size, age and gender).

The use of metal/metal conventional hip replacements peaked between 2006 and 2008 (when over 3,000 were implanted each year) and then rapidly declined, with no metal/metal THRs implanted since 2016.

The revision rate for metal/metal THRs is higher than for other bearing surfaces, but the high revision rate is mainly restricted to prostheses with head sizes >32mm.

The most common reason for revision of a primary metal/metal hip replacement is metal related pathology, followed by loosening and infection.

Metal/Metal

OUTCOME

Since 2008, metal/metal bearing surface has been shown to have a higher rate of revision compared to metal/polyethylene. In 2010, metal/metal bearing surfaces were identified as having a higher rate of revision compared to all other bearing surfaces. In the same year the important relationship between head size and revision of metal/metal prostheses was recognised.

To further evaluate the effect of head size with metal/metal bearing surface, an analysis was undertaken comparing two head size groups ($\leq 32\text{mm}$ and $>32\text{mm}$). Head sizes $>32\text{mm}$ are associated with an increased rate of revision compared to $\leq 32\text{mm}$ head sizes (Table MM2 and Figure MM2).

DEMOGRAPHICS

Metal/metal bearing surface has been used in 22,107 primary total conventional hip replacements (Table MM1 and Figure MM1).

There have been 4,992 revisions of metal/metal primary total conventional hip replacement; 600 revisions with $\leq 32\text{mm}$ and 4,392 revisions with $>32\text{mm}$ head sizes. The majority of revisions with head sizes $>32\text{mm}$ involve the acetabular component only (56.6%) followed by revision of both the femoral and acetabular components (19.1%). For metal/metal with head sizes $\leq 32\text{mm}$, revision of the femoral component is most common (29.2%), followed by revisions of the acetabular component (25.8%) (Table MM3).

The main reasons for revision of $>32\text{mm}$ head sizes are metal related pathology (46.7%), loosening (17.5%), infection (11.8%) and lysis (7.4%). The main reasons for revision of $\leq 32\text{mm}$ head sizes are loosening (26.2%), prosthesis dislocation/instability (17.0%), fracture (16.2%) and infection (13.8%) (Table MM4 and Figure MM3).

There is a relationship between age and head size. The rate of revision for head sizes $>32\text{mm}$ is higher than for head sizes $\leq 32\text{mm}$ regardless of age. For head sizes $>32\text{mm}$, patients aged <65 years have a higher rate of revision than patients aged ≥ 65 years after 4 years (Table MM5 and Figure MM4).

Both males and females have higher rates of revision when head size $>32\text{mm}$ are used, with

females having the highest rate. When head sizes $\leq 32\text{mm}$ are used, males have a lower rate of revision compared to females (Table MM6 and Figure MM5).

Regardless of head size, metal/metal has a higher rate of revision compared to metal/polyethylene. Metal/metal with $>32\text{mm}$ head sizes have a higher rate of revision compared to metal/metal with head size $\leq 32\text{mm}$ from 1 month onwards. When compared to metal/polyethylene $>32\text{mm}$ head sizes, metal/metal with $>32\text{mm}$ head sizes have a lower rate of revision from 2 weeks to 3 months followed by a higher rate of revision from 3 months onwards. Metal/metal with head size $\leq 32\text{mm}$ have a higher rate of revision compared to metal/polyethylene with head size $\leq 32\text{mm}$ (Table MM7 and Figure MM6).

The differences in the reasons for revision between metal/metal and metal/polyethylene are more evident in metal/metal prostheses with $>32\text{mm}$ head sizes (Figure MM7). Metal related pathology is largely confined to $>32\text{mm}$ head sizes. The cumulative incidence of metal related pathology at 15 years is 12.6% for head sizes $>32\text{mm}$ and 1.0% for head sizes $\leq 32\text{mm}$. The incidence of metal related pathology is potentially higher, as it is possible that undiagnosed metal related pathology contributes to the increased rate of loosening and infection reported in metal/metal prostheses with larger head sizes (Figure MM7).

In order to determine if the higher revision rate of metal/metal prostheses is prosthesis specific, all prosthesis head/acetabular combinations that have a head size $>32\text{mm}$ and have >200 procedures have been analysed. There are 13 combinations that meet these criteria. The cumulative percent revision ranges from 7.4% to 45.4% at 10 years. In comparison, there are 8 head/acetabular combinations that have head sizes $\leq 32\text{mm}$ and >50 procedures. The cumulative percent revision at 10 years ranges from 1.6% to 11.7% (Table MM8 and Table MM9).
